Hort. Dept., Fac. Agric., Ismailia, Suez Canal University

### **ABSTRACT**

Two field experiments were carried out in sandy loam soil at El-Sofia village (Private Farm), Awlad Sacker, Sharkia Governorate, Egypt on Chinese garlic (Sids-40) during the winter growing seasons of 2006/2007 and 2007/2008. The aim of this study was to study effect of soaking seed cloves in running water for 0, 24, 48 and 72hours, soaking in running water for 0, 24, 48 and 72hours, then stratification of seed cloves in wet Jute for 24 hours and the effect of cold storage of seed cloves at 7°C for 0, 1, 2 and 3weeks, before planting. The treatments also included the effect of planting date (15<sup>th</sup> August, 1<sup>st</sup> September) on plant growth, yield and its components, as well as bulbs and cloves traits. The obtained results showed that planting date (1<sup>st</sup> September) led to significant increases in all tested characteristics of dry weight, total yield and its components, as well as of bulbs quality. Soaking seed cloves in running water for 24 hours before planting led to significant increases in dry weight, total yield and its components. Moreover quality of bulbs improved compared with the control and the other treatments. Positive interaction between planting dates and soaking, soaking plus stratification and cold storage for seed cloves before planting were often observed.

**Keywords:** Garlic (*Allium sativum* L.), planting date, stratification, soaking cloves, cold storage.

### **INTRODUCTION**

Garlic (*Allium sativum* L.) is one of the oldest and popular vegetable crops in Egypt. It is one of the most important bulb crops in Egypt which is cultivated for both local consumption and export. It is commonly used as a spice or condiment as well as for medical purposes.

The pathway for improving the yield and quality of garlic is the planting date and some treatments for seed cloves before planting, such as cold storage, pre-planting cloves soaking in water and pre-planting cloves soaking in water and stratification. The early planting dates, i.e., 1<sup>st</sup> and 15<sup>th</sup> September are the best for garlic production in Lower Egypt (Maksoud *et al.*, 1984a), since the early planting leads to obtain a strong vegetative growth on which bulb yield and its quality depend. Because of the fields are still occupied in this period with the summer crops, many of the garlic growers are relatively late in garlic planting, and this would lead to evident reduction in the bulb production due to poor vegetative growth (Rahim *et al.*, 1984). Thus it would be very important to obtain good quality during such late plantation.

El-Shabasi (1988); Ahmed (2002) and Rahman *et al.*, (2004) who reported that dry weight of garlic plants (whole plants or leaves) were significantly increased when cloves were planted on 1<sup>st</sup> Sept. Cold storage and prolonged duration of pre-planting stocks induced early emergence of

cloves, increased germination percentage and enhanced crop maturity (El-Motaz *et al.*, 1967; Hwang and Kosa, 1984 and Maksoud *et al.*, 1984b). Clove differentiation was more rapid when the pre-planting storage temperature was 5C° (Rahim and Fordham, 1988 and Hwang *et al.*, 1989). Cold storage also can shorten the critical photoperiod (Takagi, 1990). It is in view of this background that this study was undertaken with the aim of exploring opportunities to improve the productivity of Chinese garlic crop cv. (Sids-40) through choice of planting date, and some pre-planting treatments of seed cloves (soaking in tap water, soaking + stratification and cold storage).

## MATERIALS AND METHODS

Two field experiments were conducted on garlic plants (Sids-40) during the winter seasons of 2006/2007 and 2007/2008 at El-Sofia village (Private Farm), Awlad Sacker, Sharkia Governorate. It aimed to study the effect of times of planting (15<sup>th</sup> August, 1<sup>st</sup> September) and effect of some pre-planting treatments (soaking seed cloves in running water for 0, 24, 48 and 72hours, soaking in running water for 0, 24, 48 and 72hours and stratification of seed cloves in wet Jute for 24 hours, and cold storage for seed cloves in a fridge at 7°C for 0, 1, 2 and 3weeks) on the dry weight, yield and bulb quality of garlic CV. Sids-40.

### 1. The experimental soil analysis

A sample of soils was randomly collected from the experimental soil at 0 to 50 cm depth, before plantation to determine the physical and chemical properties. Data of soil analysis during 2006/2007 season are presented in Table (1).

**Table (1): The physical and chemical analysis of the experimental soil during 2006/2007 season.**

Soil Properties		Soil Properties	
Physical	Value	Soluble anions	Value
Sand (%)	74.5 %	HCO <sub>3</sub> + CO <sub>3</sub> (meq/L)	6.0
Silt (%)	7.5 %	Cl <sup>-</sup> (meq/L)	5.4
Clay (%)	18 %	SO <sub>4</sub> <sup>2-</sup> (meq/L)	6.6
Texture	Sandy loam	Total N(mg/Kg <sup>-1</sup> )	56
Chemical	Value	Avial.P(mg/Kg <sup>-1</sup> )	12.0
EC (ds/m <sup>-1</sup> at 25°C)	1.80	Avial.K(mg/Kg <sup>-1</sup> )	370
pH	7.62	Organic matter (%)	1.28
		Soluble cations	Value
		Na <sup>+</sup> (meq/L)	12.5
		K <sup>+</sup> (meq/L)	0.51
		Ca <sup>2+</sup> (meq/L)	2.6
		Mg <sup>2+</sup> (meq/L)	2.4

## 2. Meteorological data

Average meteorological data for Sharkia Governorate (Abou-Kaber Station) during two growing seasons of garlic (2006/2007 and 2007/2008) are recorded in Table (2).

**Table (2): Show average meteorological data for Sharkia Governorate (Abou-Kaber Station) during the growing seasons of 2006-2007 and 2007-2008.**

Month	Average of air temperature (C°)	Average daily of relative humidity (RH %)	Soil temperature at 20 (cm)	Pan evaporation (mm/day)
	2006/2007 season			
August	30.34	66.35	27.01	5.91
September	29.09	62.83	26.76	4.62
October	26.34	63.20	23.74	3.47
November	21.66	61.43	20.81	2.58
December	17.69	64.03	16.35	2.11
January	16.09	62.94	14.31	1.58
February	17.04	65.04	15.56	2.07
March	19.11	60.74	17.45	3.23
April	22.60	57.60	20.17	4.73
2007/2008 season				
August	31.82	67.35	27.03	5.90
September	30.11	65.50	25.82	4.72
October	29.03	62.19	23.22	3.74
November	24.18	62.63	19.45	2.97
December	19.19	63.16	14.86	2.84
January	15.60	65.39	11.79	1.85
February	17.28	65.45	12.52	2.32
March	22.88	62.10	17.9	3.93
April	27.99	56.71	23.65	7.19

## 3. The experimental design and tested treatments

The experimental design was a split-plot with 3 replicates. The main-plots were devoted to the times of planting, while the sub-plots were some pre-planting of seed cloves (soaking in water, soaking + stratification and cold storage). This experiment included 24 treatments which were combination between two planting dates and 12 treatments of seed cloves before planting as shown in Schedule (1). The sub-plots area was 5.4m<sup>2</sup> which contained 3 rows each 3m long and 0.6m width. The uniformed cloves of CV. Sids-40 were chosen and planted at 10cm apart on the two sides of each row.

## 4. Cultural practice

All field plots were fertilized with 20 m<sup>3</sup> farmyard manure, 120 kg of ammonium sulphate (20.5% N), 75 kg of calcium super phosphate (15% P<sub>2</sub>O<sub>5</sub>), 72 kg of potassium sulphate (48% K<sub>2</sub>O) and 300 kg sulphur/feddan which was divided in four equal portions at these times as follows:-

- 1) 20 m<sup>3</sup> farmyard manure + 25 kg of calcium super phosphate (15% P<sub>2</sub>O<sub>5</sub>) + 150 kg sulphur + 20 kg of ammonium sulphate (20.5% N)/feddan during the soil preparation.

- 2) 50 kg of ammonium sulphate (20.5% N) + 20 kg of calcium super phosphate (15% P<sub>2</sub>O<sub>5</sub>) + 12 kg of potassium sulphate (48% K<sub>2</sub>O) + 150 kg sulphur after complete emergence.
- 3) 30 kg of ammonium sulphate (20.5% N) + 20 kg of calcium super phosphate (15% P<sub>2</sub>O<sub>5</sub>) + 24 kg of potassium sulphate (48% K<sub>2</sub>O) after one month from the second.
- 4) 20 kg of ammonium sulphate (20.5% N) + 10 kg of calcium super phosphate (15% P<sub>2</sub>O<sub>5</sub>) + 36 kg of potassium sulphate (48% K<sub>2</sub>O) after one month from the third. The control of insects and pests were used according to the instruction laid down by the Ministry of Agriculture. The harvesting time was done in the first week of March for both seasons of study.

**5. Data recorded**

The following data were recorded during the plant growth period and at harvesting date.

**5.1. Dry weight / plant**

The vegetative parts (bulbs and leaves) of chosen plants of each plot at 100, 130 and 160 days were oven dried at 70C° till constant weight and the following data were recorded.

- a. Total dry weight.  $\frac{\text{Dry weight of treatment}}{\text{Dry weight of control}} \times 100$   
b. Relative total dry weight (%) =  $\frac{\text{Dry weight of treatment}}{\text{Dry weight of control}} \times 100$

### 5.2. Total Yield

At harvesting date (the first week in March in both seasons), all plants of each plot were harvested weighed and converted to record the following data:

- a. Average yield/plant (kg).  
b. Total yield (ton/fed.).  
c. Relative total yield (%) =  $\frac{\text{Total yield of treatment}}{\text{Total yield of control}} \times 100$

### 5.3. Bulb quality

A random sample from five plants (bulb + leaves) was randomly taken from each plot at harvesting date weighed as fresh weight and bulbs were separated and weighed as fresh weight. The bulbs were oven dried at 70C° till constant weight and the following data were recorded:

- a. Average bulb and neck diameter (cm).  
b. Bulbing ratio: It was measured as reported by Mann (1952).

$$\text{Bulbing ratio} = \frac{\text{Plant neck diameter}}{\text{Bulb diameter}}$$

- c. Bulb dry matter (%) =  $\frac{\text{Bulb dry weight}}{\text{Bulb fresh weight}} \times 100$

- d. Percentage of bulb net weight =  $\frac{\text{Bulb fresh weight}}{\text{Whole plant fresh weight}} \times 100$

### 5.4. Statistical analysis

All obtained data were subjected to statistical analysis of variance according to Snedecor and Cochran (1980) and means separation was done according to the least significant difference (L.S.D) and Duncan (1958) at 5 % levels of probability.

## RESULTS AND DISCUSSION

**Dry weight/plant:** Respecting planting date, data of Table (3) declared that planting date of 1<sup>st</sup> Sept. gave higher dry weight than those planting date of 15<sup>th</sup> Aug. at 100, 130 and 160 after planting. The differences were significant in the two seasons of study, except that at 130 and 160 days in the second season, the increments were not significant.

The increase in total dry weight/plant at 160 days after planting were about 21 and 17 % for planting date at 1<sup>st</sup> Sept. over the planting date at 15<sup>th</sup>

Aug. in the 1<sup>st</sup> and 2<sup>nd</sup> seasons, respectively. These results are in accordance with those reported by El-Shabasi (1988); Ahmed (2002) and Rahman *et al.*, (2004) who reported that dry weight of garlic plants (whole plants or leaves) were significantly increased when cloves were planted on 1<sup>st</sup> Sept.

Concerning the effect of soaking cloves in water, data in Table (3) show that soaking seed cloves in water for 24 hours, insignificantly increased the dry weight of plants over the un-soaked plants or those soaked for 48 and 72 hours at 100, 130 and 160 days after planting in both seasons.

The increase in total dry weight/plant were about 3 and 12 % for soaking in water for 24hr. at 160 days after planting over the control in both seasons, respectively. Regarding soaking and stratification treatment, such data revealed that there were no significant differences among the treatments and the trend of the results were very similar to those soaked without stratification. Soaking and stratification decreased total dry weight/plant compared with control. Similar results were obtained by Osman *et al.*, (1996).

As for the effect of cold storage before planting, such data confirmed that at 100 and 130 days, the highest dry weight was obtained from plants, produced from cloves stored at 7C° for one week compared with control or with the storage period of two or three weeks. However, after 160 days of planting, data declared that cold storage decreased dry weight of garlic plants. Cold storage of cloves decreased total dry weight/plant compared to control. The reduction in dry weight was correlated with each increase in the storage period. These results coincide with those found by El-Shabasi, (1988) and Sedoguchi *et al.*, (2002).

In general, the results show that cold storage of seed cloves in a fridge at 7 C° increased dry weight/plant at early growth stage (100 days after planting), while soaking of seed cloves for 24hr. increased dry weight/plant at medium and maximum growth stages (130 and 160 days after planting) in both seasons.

As for the interaction effect of planting time and soaking cloves in water (0, 24, 48 and 72 hr.), soaking as previous and stratification for 24hr. and cold storage (Zero -one - two or three weeks) prior to planting on the dry weight of garlic plants, presented data in Table (4) show a significant interaction between treatments at 100, 130 and 160 day after planting in both seasons. Data also cleared that at 100 days, the best values were obtained from cold storage for one week with 1<sup>st</sup> Sept. planting time. At 130 and 160 days after planting, results showed that the differences among treatments of soaking or soaking and stratification were fluctuated with no definite trend. This was evident in both seasons of study. Similar results were obtained by Abd El-Hameid, (1982).

T3

**Table (4): Effect of interaction between planting date and some pre-planting treatments of seed cloves on dry weight/plant (bulb + leaves) of garlic at 100, 130 and 160 days after planting during winter seasons of 2006/2007 and 2007/2008.**

**Total yield:** Results of Table (5) show the effect of planting date, soaking of cloves in water, soaking + stratification and cold storage of cloves before planting on yield/plant and yield/fed. in 2006/2007 and 2007/2008 seasons. Concerning the effect of planting date, the data indicated that planting date at 1<sup>st</sup> Sept. gave higher yield/plant and yield/fed. (7.303 and 4.773 ton/fed. in the 1<sup>st</sup> and 2<sup>nd</sup> seasons, respectively) than those from planting date at 15<sup>th</sup> Aug. (6.027 and 3.596 ton/fed. in the 1<sup>st</sup> and 2<sup>nd</sup> seasons, respectively).

This was evident in both seasons. Similar results were obtained by Maksoud *et al.*, (1984a); Shaheen, (1987); El-Behiedi *et al.*, (1988); El-Shabbasi, (1988); Abd El-Fatah, (1989); Singh and Phogat, (1989); Orowski and Rekowski, (1993); Ajmal *et al.*, (1997); Humayun *et al.*, (1997); Ahmed, (2002); and Gupta *et al.*, (2003). They all concluded that Sept. planting gave the greatest yield with heavy bulbs.

The increases in total yield/fed. were about 17 and 32 % for planting date at 1<sup>st</sup> Sept. over the planting date at 15<sup>th</sup> Aug. in the 1<sup>st</sup> and 2<sup>nd</sup> seasons, respectively. It is obvious that the increment in total yield/fed. specially with 1<sup>st</sup> Sept. planting date., could be attributed directly, to increase in vegetative growth at such planting date, this is from one side and may be due to the climate requirements in Table 2 (temperature and photoperiod) which are available at optimum levels during Sept. month on other side. Temperatures greatly affect all the physiological processes, namely water absorption, minerals uptake, photosynthesis etc. that may be enhancing plant growth and consequently produced higher yield.

Earliest planting date gave the highest bulb weight, which may be due to plant received cool temperature for longer period which possibly increased the yield of bulb. Therefore, early grown plants produced large sized bulb resulting in the increased weight (Rahim *et al.*, 2003). Concerning the effect of soaking and soaking and stratification on garlic yield, data of Table (5) show that soaking for 24 hours increased yield/plant and yield/fed. over the control and when compared with 48 or 72 hours. The differences were significant only in the first season, while in the second one the differences were not significant.

It could be concluded that, soaking of seed cloves in tap water for 24hr. increased yield/fed. in both seasons, with no significant differences with soaking for 48hr. in both seasons. The increase of total yield were about 18 and 5 % for soaking in water over the control in the 1<sup>st</sup> and 2<sup>nd</sup> season, respectively. As for the effect of soaking and stratification, such data reveal no significant effect on the yield/plant or yield/fed. in both seasons and decreased the yield than the control. These results are coinciding with those found by Abd El-Hameid (1982) and Osman *et al.*, (1996).

Data in the same Table declared that cold storage of seed cloves at 7 C° significantly decreased the yield/plant and the yield/fed. in both seasons. The reduction on yield/plant or yield/fed. were corresponded with each increase in cold storage period. These results are in accordance with those found by Maksoud *et al.*, (1983); El-Shabbasi, (1988) and Kasim, (2002) who concluded that cold storage had adverse effect on bulb weight and total yield.

Regarding the interaction effect between planting date and soaking cloves for zero, 24, 48 or 72hr. and soaking for the same periods plus stratification in wet jute for 24 hours and cold storage for seed cloves at 7 C° for zero, one, two or three weeks, on yield/plant and yield/fed., obtained results in Table (6) declared that most treatment gave higher values with 1<sup>st</sup> Sept. than with 15<sup>th</sup> Aug. planting date. The highest values for both traits were obtained from the treatment of soaking 24 hours with 1<sup>st</sup> Sept. planting dates. The interactions between treatments of both traits were significant in both seasons. The positive interaction between planting date and soaking of seed cloves was found also by Abd El-Hameid, (1982).

**Table (6): Effect of interaction between planting date and some pre-planting treatments of seed cloves on average yield/plant (kg) and yield/feddan (ton) of garlic plants during winter seasons of 2006/2007 and 2007/2008.**

<b>L. S. D at 5 %</b>		<b>2.60</b>	<b>2.85</b>	<b>1.09</b>	<b>1.19</b>		

As for the interaction effect between planting date and cold storage on the yield of garlic, our results coincided with those of Quayouti and Kasvawi, (1995) who found significant interaction between planting date and cold storage temperature before planting.

**Bulb quality:** Data in Table (7) reveal that the diameter of bulb in the 1<sup>st</sup> season and bulb net weight (%) in the second season were higher with 1<sup>st</sup> Sept. planting date, whereas bulbing ratio in the 2<sup>nd</sup> season was higher with 15<sup>th</sup> Aug. planting date. Planting date had no significant effect on bulb dry matter (%) in both season, diameter of bulb in the 2<sup>nd</sup> season, bulbing ratio and bulb net weight (%) in the 1<sup>st</sup> season.

The favorable effect of 1<sup>st</sup> Sept. planting date on bulb diameter and dry matter percent in the bulb may be attributed to the effect of short day and low temperature at early stage of growth, followed by long photo period and high temperature during bulbing development, therefore, bulb diameter and dry weight of garlic bulb may increase (Ahmed, 2002). These results were coinciding with those reported by Shahien, (1987); El-Beheidi *et al.*, (1988); El-Shabasi, (1988); Park and Lee, (1990) and Gupta *et al.*, (2003) who concluded that Sept. planting date gave higher bulbing ratio, bulb diameter and average bulb weight (%).

It is also clear that the treatment of soaking only or soaking plus stratification for 24 hours were better than the other results in the first season. On the other hand, bulb net weight percentage and dry matter percentage showed high values from cold storage treatments for one or two weeks. Treatment of soaking or soaking and stratification indicated no clear trend among all these treatments in both seasons. These results of the interaction effect of planting date and soaking seed cloves in bulb diameter and bulbing ratio were in agreement with those of Abd El-Hameid, (1982).

Data in Table (8) illustrate the interaction effect between planting date and soaking seed cloves, soaking and stratification of cloves and cold storage of cloves before planting on bulb diameter and bulbing ratio, bulb net weight and dry matter (%) in bulb of garlic. Data declared that the interaction effect among treatments were significant and the highest values for the diameter of bulb were obtained with the soaking for 24 hours with the planting date of 15<sup>th</sup> Aug. followed by soaking for 24 hours also with the planting date of 1<sup>st</sup> Sept. in the second season. The lowest values of bulb diameters were obtained from the treatment of cold storage for three weeks at the planting date of 15<sup>th</sup> Aug. Regarding the interaction effect on bulbing ratio, data in the same Table show that the highest values were found at the planting date of 15<sup>th</sup> Aug. with soaking cloves for 24 hours in both seasons. The lowest values were noticed when the seed cloves were stored at 7C° for two or three weeks with 15<sup>th</sup> Aug. planting date in the two seasons of study.

T7

**Table (8): Effect of interaction between planting date and some pre-planting treatments of seed cloves on average diameter of bulb (cm), bulbing ratio, bulb net weight (%) and dry matter (%) of bulbs of garlic at harvesting date during winter seasons of 2006/2007 and 2007/2008.**

تأثير معاملات ما قبل الزراعة لتقاوى الثوم على الوزن الجاف والمحصول وجودة  
الأبصال تحت مواعيد زراعة مختلفة  
سمير كامل الصيفى ، محمود عبد المحسن حسن ، سوسن محمد حسن سرج و  
محمد احمد محمد على  
قسم البساتين - كلية الزراعة بالأسماعيلية - جامعة قناة السويس

أجريت تجربتان حقليتان فى ارض رملية طميية بقرية الصوفية (مزرعة خاصة) - أولاد  
صقر - محافظة الشرقية - مصر على محصول الثوم الصينى سلالة ( سدس - ٤٠ ) اثناء موسمى  
الزراعة الشتوى ( ٢٠٠٦ / ٢٠٠٧ و ٢٠٠٧ / ٢٠٠٨ ) بهدف دراسة تأثير نقع فصوص الثوم فى  
الماء الجارى لمدة صفر ، ٢٤ ، ٤٨ ، ٧٢ ساعة ، النقع فى الماء الجارى لمدة صفر ، ٢٤ ، ٤٨ ،  
٧٢ ساعة ثم كمر فصوص الثوم فى الجوت الرطب لمدة ٢٤ ساعة وتأثير التخزين البارد  
لفصوص الثوم عند ٧ درجة مئوية لمدة صفر، ١ ، ٢ ، ٣ أسابيع ، كل هذه العوامل قبل الزراعة  
بالإضافة الى تأثير ميعاد الزراعة ( ١٥ أغسطس ، ١ سبتمبر ) . على الوزن الجاف والمحصول  
ومكوناته وجودة الأبصال. أوضحت النتائج المتحصل عليها ان الزراعة فى ١ سبتمبر ادت الى  
زيادة معنوية فى كل صفات الوزن الجاف والمحصول الكلى ومكوناته وجودة الأبصال . أدى نقع  
فصوص الثوم فى الماء الجارى لمدة ٢٤ ساعة قبل الزراعة لزيادة معنوية فى الوزن الجاف  
والمحصول الكلى ومكوناته كما أدت الى تحسين جودة الأبصال مقارنة مع معاملة الكنترول  
والمعاملات الأخرى. لوحظت التفاعلات الموجبة بين مواعيد الزراعة ومستويات كلا من النقع  
والتخزين البارد لفصوص الزراعة قبل الزراعة فى حالات كثيرة.
