

ESTIMATION AND DISTRIBUTION OF WEED FLORA IN STRAWBERRY (*Fragaria ananassa* DUCHESNE) FIELDS IN EGYPT.

EI-Khanagry, S. S. G.

Flora and Phyto-Taxonomy Res. Sec., Hort. Res. Inst., A.R.C., Giza, Egypt.

ABSTRACT

Weeds are considered a problem in strawberry production areas in Egypt. This study on weed flora is carried out on two methods for strawberry production. The first is located in West Delta area and Qalubia governorate where the soils fumigated by methyl-bromide (protected cultivation) and the second is in Qalubia, Sharkia and Ismailia governorates where the soils were not fumigated (normal cultivation). The study was conducted during winter seasons from 2000/2001 to 2003/2004. Weeds were estimated randomly on one square meter as random and replicated ten times in every fields. Six parameters were used for evaluated weed species, namely the relative density, general density, general frequency, percentage of infested fields, cumulative number and abundance. The results appeared that, total of 112 species were recorded, belonging to 78 genera and 31 families. Species *Artemisia vulgaris*, *Galinsoga parviflora*, *Oxalis latifolia* and *Urochloa panicoides* were recorded as new species introduced to Egyptian flora. While, species *Chenopodium murale*, *Conyza bonariensis*, *Cyperus rotundus*, *Digitaria sanguinalis*, *Melilotus indicus*, *Nothoscordum inodorum*, *Oxalis corniculata*, *Poa annua*, *Polypogon monspeliensis*, *Portulaca oleracea*, *Sonchus oleraceus*, *Stellaria media*, *Trianthema portulacastrum* and *Trifolium resupinatum* were evaluated as the most troubous weeds. In addition, the effect of methyl-bromide on legume seeds germination were less than other species.

INTRODUCTION

Strawberry is an important export and cash vegetable crop in Egypt. Cultivated area about 2000 hectares. It is cultivated by two dominant methods, Protection cultivated (fresh) and normal cultivation (frigo). The dominant pests in the strawberry were; nematodes, mites, insects and weeds. Nematodes were controlled by methyl bromide or crop rotations, while mites and insects were controlled by chemical compounds and biocontrol methods. Weeds were controlled essentially by mechanical methods; rarely by herbicides.

Distribution and types of strawberry weeds are not clear. The cultivation of strawberry season in Egypt starts from August or September to May or June. The summer weeds were growing at the beginning and ending of season, and winter weeds were growing at winter months, while many perennial weeds were growing during the whole season.

Atkinson et al. (1983) in UK, surveyed the weeds of strawberry and reported that the most spreadable weed species were; *Convolvulus arvensis*, *Agropyron repens*, *Cynodon dactylon*, *Paspalum dilatatum* and *Sorghum halepense*, while in Ireland, MacGiolla et al. (1989) reported that, the dominant weeds were *Epilobium montanum*, *Senecio vulgaris* and *Viola arvensis*. Nonnecke et al. (1993) and Quarles (1999) in USA found in strawberry fields the following weeds; *Rumex crispus*, *Chenopodium album*, *Amaranthus retroflexus*, *Portulaca oleracea*, *Solanum nigrum*, *Plantago*

lanceolata, *Agrostis palustris*, *Digitaria sanguinalis*, *Setaria pumila* and *S. viridis*.

Abd El-Raouf et al. (1993) identified the most dominant winter weeds in Egypt; *Anagallis arvensis*, *Avena fatua*, *A. sativa*, *Beta vulgaris*, *Capsella bursa-pastoris*, *Chenopodium murale*, *Coronopus squamatus*, *Phalaris paradoxa*, *Polypogon monspeliensis*, *Rumex dentatus* and *Sonchus oleraceus*. While, Aboustait et al. (1993) in Egypt, observed the major summer weeds; *Amaranthus hybridus*, *A. viridis*, *Brachiaria reptans*, *Corchorus olitorius*, *Cyperus rotundus*, *Digitaria sanguinalis*, *Dinebra retroflexa*, *Echinochloa colona*, *Leptochloa panicea*, *Portulaca oleracea* and *Trianthema portulacastrum*. The new weeds records by Daie and El-Khanagry (2004) included some dangerous weeds and may caused problems in the future, these weeds are; *Urochloa panicoides*, *Trianthema portulacastrum*, *Cenchrus echinatus*, *Acrachne racemosa*, *Digitaria ciliaris*, *Commelina benghalensis*, *Leptochloa panicea*, *Eragrostis pilosa* and *Tribulus terrestris*. Culpepper et al. (2004) reported that, *Commelina benghalensis* was the first weed species observed in United States in 1928 and distributed as most troublesome cotton weed's in many states.

The sensitivity of weeds to methyl-bromide was very differed among species. Zhang et al. (1997) and Unruh et al. (2002) found that, methyl bromide provided 100 % control of *Cyperus rotundus*, *C. esculentus*, *Lolium multiflorum* than *Portulaca oleracea*, *Abutilon theophrasti* and *Brassica kaber*, while, lesser effect on *Mollugo verticillata*. The effect of fumigation in controlling weeds depended on the moisture and temperature of the soil. Amer et al. (1998) reported that *Vicia faba* seeds were fumigated with 50 and 100 g/m² methyl bromide for 4 h, 1, 2, 3 and 4 days, the seed germination decreased with increased the rates and time of application.

Most species of genus *Amaranthus* distributed as annoyed weeds in cultivated lands especially in summer crops. Grichar (1997) showed that *Amaranthus palmeri* decreased the yield of peanut between 25-60 % compared with the yield controlled by herbicides. While, Massing and Currie (2002) studies the impact of *A. palmeri* on corn. They reported that, *A. palmeri* declined the grain yields from 11 to 74 % compared weed free yields. Moreover, Massing et al. (2003) found that *A. palmeri* decreased the leaf area of corn 5-15 % and 60-80 % of light was intercepted above the ground. On the other hand, Bensch et al. (2003) arranged descendingly the effect of different *Amaranthus* species on soybean yield as the following *A. palmeri*, *A. hybridus*, *A. retroflexus*, *A. rubis*, *A. bilitoides* and *A. viridis*. In addition, Moore et al. (2004) evaluated the effects of *A. palmeri* on grain of sorghum, found that grain yield decreased by 1.8 to 3.5 % by increasing one weed plant per 15 m at each row. Also, each 1 kg of *A. palmeri* dry weight reduced grain yield by 5-9 %.

MATERIALS AND METHODS

Weed survey on strawberry fields was started from December to May during 2000/2001 to 2003/2004. The area of study included protected cultivation in great farms at west Delta area and Qalubia governorate. Every farm was divided into sections as fields; number of fields were 112 and 51

fields at west Delta and Qalubia, respectively. Soils of these fields were fumigated by methyl bromide at 50-70 g/m² to control the nematodes. The normal cultivation fields were 142 at Qalubia, 45 at Sharkia and 86 at Ismailia. These fields were not fumigated, but the crop rotation system used as antinematicides.

Weeds were estimated more than once at different times. Ten individual square meter were chosen randomly in each field. Weeds identification and distribution were conducted according to Täckholm (1974), Cope and Hosni (1991), El-Hadidi and Fayed (1994/65) and Boulos (1999, 2000 and 2002).

The following equations used for evaluation the weeds associated with strawberry :

Relative density (R.D.) % =

$$\frac{\text{Total number of individual plant of every species}}{\text{Total plants number of all species}} \times 100$$

$$\text{General density (G.D.) (plant/m}^2\text{)} = \frac{\text{Total plant number of every species}}{\text{Number of fields} \times \text{sample size of field}}$$

General frequency (G.F.) % =

$$\frac{\text{Total number of infested square meter for every species}}{\text{Number of all field} \times \text{sample size of field}} \times .100$$

$$\text{Infested field (I.F.) \%} = \frac{\text{Number of infested fields by every species}}{\text{Total number of fields}} \times 100$$

Cumulative number :

The results of the previous equations transferred to symbols and had numbers depend on the following scale which used by Abd El-Raouf et al. (1993), Aboustait et al. (1993) and El-Mashad (2001).

Dominant (o) > 5 % RD

> 5 plant/m² GD

> 20 % GF and IF

Common (c) > 1-5 % RD

> 1-5 plant/m² GD

> 10-20 % GF and IF

Rare (b) > 0.1-1 % RD

> 0.1-1 plant/m² GD

> 1-10 % GF and IF

Very rare (a) > 0.1 % RD

> 0.1 plant/m² GD

> 0.1 % GF and IF

Every symbol transferred again to absolute numbers as follows; d = 4, c = 3, b = 2 and a = 1, then from these numbers of very species counted the cumulative number.

Abundance parameter :

Cumulative number divided into four sets for defined the abundance as follows: Dominant (13-15), very common (10-12), common (7-9), and rare (4-6).

Different parameters were recorded for weeds evaluation, i.e. Kershaw (1975), Shaltout and El-Fahar (1991) and Hassanein et al (1997) used the relative density to find a relation between recorded weed species, while Abd El-Raouf et al. (1993) and Hassanein et al. (1997) used the general density to evaluate the density of every species per square meter. On the other hand, El-Mashad et al. (2002) and Sherif (2002) used the general frequency equation to estimate the distribution of every species. Moreover, Attalla (2002) and Daei and EI-Khanagry (2004) applied the infested field equation to evaluate the distribution of every species in the different study area. Meanwhile, EI-Khanagry (1993) and Colbasch (2000) used cumulative number to count different parameters in one measure. In addition, Abd El-Ghany (1981), Marshall (1988), McCulty et al. (1991) and Hassan and Mohamed (1992/93) used abundance parameter for arranging the species in sequence sets.

RESULTS AND DISCUSSION

The recorded weed species in all strawberry fields appeared in Table (1). The total weeds were 112 species belong to 78 genera and 31 families. One species belongs to Conifer group; Dicots taxa were 80 species divided into 11 perennial and 69 annual weeds. Annual weeds classified to 14, 53, 2 species as summer, winter and all year plants, respectively; Monocots taxa were 31 species classified to 6 perennial and 25 annual weeds. Annual weeds classified to 8, 14 and 3 as summer, winter and all year plants; respectively. The sequence of families according and their species were; Gramineae (26), Compositae (17), Cruciferae (10), Leguminosae (8), Amaranthaceae (6), Chenopodiaceae (5), Polygonaceae (3), Caryophyllaceae (3), Euphorbiaceae (3), Malvaceae (3), Scrophulariaceae (3), Oxalidaceae (2), Umbelliferae (2), Plantaginaceae (2) & Juncaceae (2). The others 17 families included one species only.

The new record plants as weeds from Egyptian flora in the cultivated area were *Boerhavia diffusa*, *Bassia indica*, *Rorippa integrifolia*, *Cyananchum acutum*, *Misopates orontium*, *Veronica* spp., *Lactuca serriola*, *Launea nudicaulis*, *Symptorichum squamatus*, *Juncus bufonius*, *Commelina benghalensis*, *Bromus catharticus*, *Cenchrus echinatus*, *Digitaria ciliaris*, *Eragrostis* spp. In addition, the new species introduced to Egyptian flora were *Oxalis latifolia*, *Artemisia vulgaris*, *Galinsoga parviflora*, *Nothoscordum inodorum* and *Urochloa panicoides*. Moreover, some desert plant recorded in strawberry fields, i.e., *Artemisia monosperma* and *Parapholis incurva*; while *Cusuarina* sp., *Tamarix* sp. and *Juncus acutus* registered as occasionally species. The new distribution of old Egyptian flora were *Trianthem portulacastrum*, *Amaranthus blitoides*, *A. palmeri* and *Commelina benghalensis*. Moreover, *Orobanche aegyptiaca* collected as abnormal weed, it parasitized on *Ammi majus* and *Sonchus oleraceus*.

P : perennial, S : annual summer weeds, W : annual winter weeds, A : all year (given more one generation in the year).

1- Normal cultivation:

Table (2) shows the weed flora recorded in strawberry fields at Qalubia, Sharkia and Ismailia governorates.

1.1- Qalubia governorate:

Number of weeds were 70 species belongs to 53 genera and 26 families.

1.1.1- Relative density (R.D.): The highest percentage of families recorded by Oxalidaceae (17.139%), Graminae (16.320%), Alliaceae (10.261%), Cyperaceae (8.172%). Total percentages of these families were (51.892%). The percentages of Caryophyllaceae, Umbelliferae, Portulaceae, Chenopodiaceae, Compositae, Aizoaceae, Cruciferae, Scrophulariaceae, Leguminosae and Polygonaceae were between 1-5 %, the total of these families were 30.366 %. Meanwhile, the very common species were *N. inodorum*, *Oxalis corniculata*, *Cyperus rotundus* and *O. latifolia*. While, 12 species were appeared as common weeds, 26 as rare and 23 as very rare species.

1.1.2- General density (G.D.): *C. rotundus*, *N. inodorum* and *Oxalis spp.* were recorded as common weeds and 25 species as rare weeds and 41 species as very rare weeds. The density mean of all species was 19.682 plant/m².

1.1.3- General frequency (G.F.): Species were registered as very common weeds. *N. inodorum*, *Poa annua* and *Stellaria media*, the other species distributed as common, rare and very rare weeds (8, 25 and 33 species); respectively.

1.1.4- Infested fields (I.F.): Results obtained indicated that the highest percentages of infestation were by *Poa annua*, *C. rotundus*, *Capsella bursa-pastoris*, *Sonchus oleraceus*, *N. inodorum* and *O. corniculata*. The other very common weeds (27 species) were less than 50 %. Meanwhile, the remainder species appeared as common, rare and very rare weeds (11, 29 and 35 species), respectively.

1.1.5- Cumulative number (C.U.): High cumulative number recorded by *N. inodorum*, *O. corniculata* and *O. latifolia*.

1.1.6- Abundance (A.B.): Six dominant species found in the strawberry fields at Qalubia, they were *C. rotundus*, *N. inodorum*, *O. corniculata*, *O. latifolia*, *P. annua* and *S. media*. On the other hand, the remainder species were divided into 21 very common, 18 common and 20 rare species.

1.2- Sharkia governorate:

The number of families recorded at Sharkia governorate were 24 included 45 genera and 57 species.

1.2.1- Relative density: The highest percentages of (RD) were for families; Graminae (22.190%), Cyperaceae (19.792%), Portulaceae (15.583%), Amaranthaceae (7.193%) and Caryophyllaceae (5.968%). The total percentage of these families were 70.726 %. The other families which represented more than 1 % were Cruciferae, Aizoaceae, Compositae, Chenopodiaceae, Primulaceae, Scrophulariaceae and Leguminosae. The total percentage of these families were 19.584%. The total percentage of the remainder families were 9.69 %. The very common species were *Amaranthus viridis*, *C. rotundus*, *Chenopodium murale*, *P. oleracea*, *P. annua* and *S. media*.

Table (2): Estimated weed flora in normal cultivated method of strawberry field at Qalubia, Sharkia and Ismailia Governorates by relative density (%), general density (plants/m²), general frequency (%), Infested field (%), cumulative number and abundance.

RD = Relative density ($\times 10^{-3}$), GD = general density ($\times 10^{-3}$), GF = general frequency ($\times 10^{-2}$), CU = cumulative value, AB = abundance, D = dominate, V = very common, C = common, and R = rare.

* Less than $\times 10^{-3}$.

1.2.2- General density: Species of *A. viridis*, *C. rotundus*, *P. annua* and *P. oleracea* appeared as common weeds. Also, 13 and 30 species were recorded as rare and very rare weeds, respectively. The density mean of all species was 13.492 plants/m².

1.2.3- General frequency: The highest very common species found were *A. viridis*, *C. cornutus*, *P. oleracea* and *S. media*. However, the other species divided to 8 common, 26 rare and 19 as very rare weeds.

1.2.4- Infested fields: The species which were infested more than 60% of the total studied fields were : *C. rotundus*, *P. oleracea*, *A. viridis*, *P. annua* and *Digitaria sanguinalis*. In addition, 13 species were infested less than 60 %. The common and rare weeds were 11 and 23 species, respectively.

1.2.5- Cumulative number: The following species *A. viridis*, *C. rotundus*, *P. oleracea* and *S. media* gave the highest (CU) than the other species.

1.2.6- Abundance: The dominant species were *A. viridis*, *C. rotundus*, *P. oleracea*, *S. media* and *C. murale*. The very common and rare weeds were 15, 21 and 18 species, respectively.

1.3- Ismailia governorate:0

The number of weed species were 72 species belonging to 56 genera and 24 families.

1.3.1- Relative density: The highest total percentage of families were Cyperaceae (33.189%), Graminae (19.743%), Portulaceae (9.611%), Amaranthaceae (9.106%), Oxalidaceae (8.732%), Primulaceae (7.287%), Cruciferae (6.138%) and Chenopodiaceae (6.129%). The other families which obtained more than 1.0 % were Caryophyllaceae, Leguminosae and Compositae. The very common weeds were *C. rotundus*, *P. oleracea*, *P. annua*, *O. corniculata*, *A. arvensis* and *A. viridis*; Other species classified to 17 common, 32 rare and 14 very rare weeds.

1.3.2- General density: Four species appeared as common weed, they were *C. rotundus*, *O. corniculata*, *P. annua* and *P. oleracea*. Also, 29 and 38 species were found as rare and very rare weeds. The density mean of all species was 13.492 plants/m².

1.3.3- General frequency: Results obtained indicated that, the very common species were *C. rotundus*, *P. annua* and *P. oleracea*. The remainder species were classified to 5 common, 33 rare and 30 very rare weeds.

1.3.4- Infested fields: Data clearly showed that, the very common species which infested more than 50 % of the fields were *C. rotundus*, *P. annua*, *P. oleracea*, *A. arvensis* and *S. media*. The other very common weeds less than 50 % were 20 species. The common, rare and very rare weeds were 12, 33 and 1; respectively.

1.3.5- Cumulative number : The highest (CU) registered by *P. annua*, *P. oleracea* and *C. rotundus*.

1.3.6- Abundance: The following species appeared as dominant weeds; *A. viridis*, *A. arvensis*, *C. rotundus*, *O. corniculata*, *P. annua* and *P. oleracea*. The other species which found as very common, common and rare weeds were 33, 13 and 29; respectively.

The previous results could be summarized as follows : The important species found at Qalubia governorate only were; *O. latifolia*, *Galinsoga*

RD = Relative density ($\times 10^{-3}$), GD = general density ($\times 10^{-3}$), GF = general frequency ($\times 10^{-2}$), IF = infested field ($\times 10^{-2}$), CU = cumulative value, AB = abundance, D = dominate, V = very common, C = common, and R = rare.

2.2.3- General frequency: The only species appeared as very common weeds was *T. resupinatum*, while *P. oleracea* and *C. rotundus* recorded as common weeds. The remainder 29 and 23 species registered as rare and very rare weeds; respectively.

2.2.4- Infested fields: The following species had highest percentages of infested fields; *T. resupinatum*, *P. oleracea*, *C. bonariensis*, *S. oleraceus* and *M. indicus*. The other very common distribution species less than 40 %. Meanwhile, infested fields by common, rare and very rare weeds were 12, 29 and 2 species, respectively.

2.2.5- Cumulative number: *C. bonariensis*, *P. oleracea* and *M. indicus* were registered highest (CU).

2.2.6- Abundance: The dominant weeds were *C. bonariensis* and *T. resupinatum*. Meanwhile, 11 species were found as very common weeds, 15 as common weeds and 25 as rare weeds.

The previous results indicated that, the dominant species in West Delta farms were *C. bonariensis*, *M. indicus*, *T. resupinatum* and *E. pilosa*. These species except *E. pilosa* were found at Qalubia; also, in addition to *P. oleracea*.

3- Comparison between normal and protected cultivation :

Table (4) shows the all species recorded in strawberry fields with their different parameters.

3.1- Normal cultivation :

104 species recorded in the normal cultivated fields. These species belong to 70 genera and 29 families, these families which included high number of species were : Graminae (22), Compositae (12), Cruciferae (9), Leguminosae (8), Amaranthaceae (6), Chenopodiaceae (5), Scrophulariaceae (3), Euphorbiaceae and Oxalidaceae (2). Also, 20 families each included one species only.

3.1.1- Relative density : The families which showed high percentage were Cyperaceae (16.139%), Graminae (11.928%), Oxalidaceae (9.663%), Portulacaceae (7.217%), Alliaceae (5.753%) and Chenopodiaceae (5.541%). The following families registered percentage between 1-5 %; Caryophyllaceae, Amaranthaceae, Cruciferae, Primulaceae, Compositae, Leguminosae, Scrophulariaceae, Umbelliferae, Aizoaceae and Polygonaceae. Meanwhile, the dominant weeds that have high percentages were *C. rotundus* (16.139%), *P. oleracea* (7.217%), *P. annua* (6.638%), *N. inodorum* (5.753%) and *O. corniculata* (5.440%). Number of species appeared as common, rare and very rare weeds were 19, 32 and 36 species; respectively.

3.1.2- General density: The common species were *C. rotundus*, *P. oleracea* and *P. annua*. Also, species recorded as rare and very rare weeds were 32 and 57. The general density mean of all species was 17.029 plants/m².

3.1.3- General frequency: The sequence of very common weeds were *P. annua*, *P. oleracea*, *S. media* and *N. inodorum*. Other species recorded as common (7), rare (31) and very rare (40).

3.1.4- Infested fields: Species that infested more than 50 % from all fields studied were; *S. media*, *C. rotundus*, *A. arvensis* and *S. oleraceus*; while, 16

species recorded as dominant weeds were less than 50 %. Other species distributed as common (18), rare (41) and very rare (9).

3.1.5- Cumulative number: High CU obtained by *P. annua*, *P. oleracea* and *N. inodorum*.

3.1.6- Abundance: The high abundance species recorded by *P. annua*, *P. oleracea*, *N. inodorum*, *C. rotundus*, *O. corniculata* and *S. media*. Other species distributed as very common (24), common (25) and rare weeds (41).

3.2- Protected cultivation :

Total weeds were 88 species. They belong to 64 genera and 26 families. The greater number of species classified under the following families : Graminae (17), Compositae (14), Leguminosae (8), Amaranthaceae (6), Cruciferae (5), Chenopodiaceae, Malvaceae and Euphorbiaceae (3), Polygonaceae and Caryophyllaceae (2). On the other hand, 16 families each included one species.

3.2.1- Relative density : Families of higher percentages were : Cyperaceae (16.139%), Graminae (11.928%), Oxalidaceae (9.663%), Portulacaceae (7.217%), Alliaceae (5.753%) and Chenopodiaceae (5.541%). Ten families gave percentage ranged from 1-5 %. They were Caryophyllaceae, Amaranthaceae, Cruciferae, Primulaceae, Compositae, Leguminosae, Scrophula-riaceae, Umbelliferae, Aizoaceae and Polygonaceae. Meanwhile, a very common weeds which had the highest percentages were *C. rotundus* (16.139%), *P. oleracea* (7.217%), *P. annua* (6.638%), *N. inodorum* (5.751%) and *O. corniculata*. Another species classified as common (19), rare (32 and very rare weeds (36).

3.2.2- General density : The species; *C. rotundus*, *P. oleracea* and *P. annua* appeared as common weed. Also, 32 and 57 species were recorded as rare and very rare weeds; respectively. The general mean of all species was 17,029 plants/m².

3.2.3- General frequency : The sequence of very common weeds were *P. annua*, *P. oleracea*, *S. media* and *N. inodorum*. Other species recorded as 7 common, 31 rare and 40 species very rare weeds.

3.2.4- Infested fields : Species which distributed in more than 50 % of the studied fields were : *S. media*, *C. rotundus*, *P. annua*, *A. arvensis* and *S. oleraceus*; while, 16 species recorded as common weeds infested less than 50 % of all fields. Other species distributed as common (18), rare (14) and very rare (9).

3.2.5- Cumulative number : The species; *P. annua*, *P. oleracea*, *O. corniculata* and *S. media* gave high number of CU followed by *N. inodorum*.

3.2.6- Abundance : The species; *P. annua*, *P. oleracea*, *N. inodorum*, *C. rotundus*, *O. corniculata* and *S. media* appeared high abundance. Number of species of very common, common and rare weeds were 24, 21 and 41 species; respectively.

This study showed the new species records, new phytogeographical of some old Egyptian flora, new weeds infested the cultivated lands in Egypt, and the effect of the agricultural practices on the weeds.

The new recorded species added to the Egyptian flora were *Artemisia vulgaris*, *Galinsoga parviflora*, *Oxalis latifolia* and *Urochloa panicoides*. These results depended on what Tackholm (1974), Cope and Hosni (1991), El-Hadidi and Fayed (1994-95), and El-Khanagry (1993 & 2005) had reached in this concern.

Table (4): Estimated weed flora in strawberry under different cultivated method by relative density (%), general density (plants/m²), general frequency (%), infested field (%), cumulative number and abundance.

New distribution of some old Egyptian flora were represented *Amaranthus blitoides*, *Commelina benghalensis*, *Cynanchum acutum* and *Trianthema portulacastrum*. This result was in accordance with Tackholm (1974), El-Hadidy (1980), Mahgoub (1985 & 1993), Soliman (1989), Abousteit et al. (1993), Boulos (1995 & 1999) and El-Khanagry (2004).

The new species which were not appeared as weeds in cultivated lands and recorded in this investigation, were *Bassia indica*, *Bromus catharticus*, *Commelina benghalensis*, *Cynanchus acutum*, *Eragrostis ciliaris*, *E. pilosa*, *Juncus bufonius*, *Launaea nudicaulis*, *Reichardia tingitana*, *Rorippa palustris*, *Rumex crispus* and *Trigonella facinata*. These results were in agreement with Tackholm (1974), Abd El-Raouf et al. (1993), Abousteit et al. (1993), El-Hadidi and Fayed (1994/95), Boulos (1999, 2000 & 2002), Culpepper et al. (2004), Dale and El-Khanagry (2004) and El-Khanagry (2004 & 2005).

Soil treated by methyl bromide controlled or inhibited the germination of many species as *Amaranthus hybridus*, *A. viridis*, *Ammi majus*, *Anagallis arvensis*, *Capsella bursa-pastoris*, *Cyperus rotundus*, *Oxalis corniculata*, *Phalaris minor*, *P. paradoxa*, *Poa annua*, *Rumex dentatus*, *Setaria viridis*, *Sisymbrium irio*, *Stellaria media* and *Trianthema portulacastrum*. Meanwhile, legume seeds group, i.e., *Medicago intertexta*, *M. polymorpha*, *Melilotus indicus*, *M. serratifolius* and *Trifolium resupinatum* were not affected by methyl bromide. These results may be referred to the time of fumigation on July and August. These results were confirmed by Amer et al. (1998) and Unruh et al. (2002).

The dominant species in different strawberry fields were *Chenopodium murale*, *Conyza bonariensis*, *Cyperus rotundus*, *Digitaria sanguinalis*, *Melilotus indicus*, *Nothoscordum inodorum*, *Oxalis corniculata*, *Poa annua*, *Polypogon monspeliensis*, *Portulaca oleracea*, *Sonchus oleraceus*, *Stellaria media*, *Trianthema portulacastrum* and *Trifolium resupinatum*. Many of these species were reported by Atkinson et al. (1983), MacGiolla et al. (1989), Nonnecke et al. (1993) and Quarles (1999).

In addition, this study may document most of weeds found in strawberry fields, representing the new weeds and helping to find the suitable methods to controlling these weeds in the future.

مثل الحشائش مشكلة هامة في مناطق إنتاج الفراولة بمصر. أجريت دراسة حصر الحشائش لنظامين لإنتاج الفراولة. الأولى تقع في غرب الدلتا ومحافظة القليوبية حيث تixer التربة ببروميد الميثيل (الزراعة الحديثة)، والطريقة الثانية تقع في محافظات القليوبية والشرقية والإسماعيلية حيث لا يتم تixer التربة (الزراعة التقليدية). أجريت الدراسة خلال مواسم الشتوة بداية من عام ٢٠٠١/٢٠٠٠ وحتى ٢٠٠٤/٢٠٠٣. وتم تقدير الحشائش في مساحة ١ متر مربع عشوائياً ومكرراً ١٠ مرات في كل حقل. واستخدمت ستة معايير لتنبيئ أنواع الحشائش. تلك المعايير عبارة عن: الكثافة انمطالة، والكثافة العامة، والتكرار العام، ونسبة الحقول المصابة، والمعد التراكمي، والوفرة. أظهرت الدراسة أن مجموع الأنواع المسجلة ١١٢ نوعاً تتبع ٧٨ جنساً و ٣١ فصيلة. سجلت الأنواع ارتيميزيا فولجارييس، الجالينيزوجا بارفيفلورا، الأوكساليس لاتيفوليا، البوروكلورا باتيكيلوينس كأنواع جديدة في الفلورا المصرية. بينما قيمت الأنواع المنتجة، حشيشة الجبل، السعد، النغير، القفل، النرجس، الحامض، البواء، ديل القسط، الرجلة، الجعوضيض، الفزانة، الرجلة السوداني والقرط كأهم الحشائش الضارة. بالإضافة إلى أن تأثير بروميد الميثيل كان أقل تأثيراً على إنبات البذور البقوية عن بقية الأنواع.
