### Effect of some Treatments Stimulating Growth and Yield on Pea Plants Grown under High Temperature Conditions

Hoda I. A. Ahmed\* and E. E. I. Taha

Horticulture Research Institute, Agriculture Research Centre, Giza, Egypt

#### ABSTRACT

To investigate the impact of some stimulants on the pea plants grown under high-temperature conditions, a field experiment was conducted to assess the effects of vitamin C, melatonin, potassium citrate, and cytokinin, in addition to a control group that did not receive any spray, on pea cultivars including A (master b), B (sweet 1), and C (sweet 2), which were assigned to the main plots. While, the stimulants were arranged in the sub-main plots. The experiment measured various growth and yield parameters, including plant height, leaf area, fresh and dry weights, chlorophyll content, carotene content, days required for fruit setting, No. of pods, pod length, pod yield and protein content. The results showed that the cultivar "C" performed the best across all studied treatments, except for days required for fruit setting. Following "C" cultivar, the performance of cultivar "B" was observed to be superior, while cultivar "A" ranked third in terms of growth and yield characteristics. In terms of fruit setting, cultivars "A" and "B" exhibited early fruit setting, whereas cultivar "C" experienced a delay in fruit set. Regarding the stimulants, spraying cytokinin yielded the highest values for all the studied characteristics. Potassium citrate treatment ranked second in terms of performance, followed by melatonin then vitamin C treatments, respectively, while the control group showed the lowest values. Overall, the application of cytokinin had the most positive impact on the growth and yield of pea plants under high-temperature conditions. Other studied stimulants also had positive effects, although to a lesser extent.

**Keywords:** Vitamin C, melatonin, potassium citrate, cytokinin

#### INTRODUCTION

Garden peas (*Pisum sativum* L.) plants hold significant importance in terms of economic and food aspects in Egypt. Pea cultivation contributes to the agricultural economy of Egypt. The production and sale of peas provide income for farmers and support rural livelihoods (Mileek and Mahmoud, 2021). The pea industry also generates employment opportunities, including farm labor, transportation, packaging, and processing. Egypt has the potential to export peas to international markets (Abo-Hamda, 2019). With proper cultivation and quality control practices, Egyptian peas can meet the demands of foreign markets, contributing to foreign exchange earnings and expanding trade opportunities. Peas are a valuable source of nutrition and play a vital role in addressing food security in Egypt (Abou-El-Hassan and Elbatran, 2020). They are a rich source of protein, dietary fiber, vitamins (such as vitamin C, vitamin A, and B-vitamins), minerals (including iron and potassium), and antioxidants (Guo *et al.*, 2020). Peas provide essential nutrients to the population, especially when included in a balanced diet. Peas are commonly used as a rotational crop in Egyptian agriculture. They have nitrogen-fixing properties, meaning they can convert atmospheric nitrogen into a usable form for plants (Abi-Ghanem *et al.*, 2011). This helps improve soil fertility and reduces the reliance on synthetic fertilizers, leading to sustainable agricultural practices (Knight, 2012). The Ministry of Agriculture in Egypt, specifically the Agriculture Extension services, reported that during the 2019 winter season, the cultivated area for green peas in Egypt covered 46,889 feddan. This cultivation resulted in a total production of 199,138 metric tons, with an average yield of 4.35 metric tons per feddan. It is noteworthy that

the Egyptian government has formulated a strategy with the objective of expanding the area dedicated to pea cultivation, as mentioned by Slima and Ahmed (2020).

Under high-temperature conditions, pea plants can experience various physiological and metabolic changes that negatively affect their growth and yield (Sousa-Majer *et al.*, 2004). Heat stress often leads to the accumulation of reactive oxygen species (ROS) in plant tissues, causing oxidative damage (Abdulmajeed *et al.*, 2017; Osorio *et al.*, 2023). However, certain treatments can help stimulate growth and improve yield even in such adverse conditions. Plant breeders have developed heat-tolerant pea cultivars that are better adapted to high-temperature conditions. These cultivars possess genetic traits that enable them to withstand heat stress and maintain better growth and yield compared to traditional varieties (Sharma *et al.*, 2022). Also, certain growth regulators, such as cytokinins can stimulate plant growth and yield even under high-temperature conditions (Abd El-Hady *et al.*, 2016; Mok, 2019), as this hormone promotes cell division, elongation, and flowering, which can enhance the overall productivity of pea plants. On the other hand, the application of antioxidants, such as ascorbic acid (Hamil *et al.*, 2015; Noufal, 2018) or melatonin (Yusuf *et al.*, 2020; EL-Bauome *et al.*, 2022; El-Beltagi *et al.*, 2023), can help scavenge ROS and protect pea plants from oxidative stress. Also, the application of chemical compounds such as potassium citrate, a combination of potassium and citric acid, can improve nutrient uptake, root growth, and stress tolerance in pea plants (Gebaly *et al.*, 2013).

It's important to note that the effectiveness of these treatments may vary depending on the severity and duration of high-temperature conditions, as well as the specific cultivar of the

pea plant being grown. So, the aim of the current research work was to evaluate the response of three cultivars of pea plants grown under high-temperature conditions to some growth stimulants.

## MATERIALS AND METHODS

### 1. Experimental Site.

The present research was conducted at the Experimental Farm of the Agricultural Research Center (ARC) located in Paramon Village, Mansoura City, Egypt. The soil at the experimental site is characterized by a clayey texture, comprising 24.14% sand, 26.20% silt, and 49.66% clay. The pH of the soil is 8.10, and its electrical conductivity (EC) value is 2.75 dSm<sup>-1</sup>. The available nutrient levels in the soil are as follows: 45 mg kg<sup>-1</sup> of nitrogen (N), 7.60 mg kg<sup>-1</sup> of phosphorus (P), and 220 mg kg<sup>-1</sup> of potassium (K). The initial soil analysis was performed according to the methods described by Dane and Topp (2020) and Sparks *et al.* (2020).

### 2. Pea seeds and substances studied

Pea seeds [Cv A (master b), B (sweet 1), and C (sweet 2)] were acquired from the ARC, while vitamin C, melatonin, potassium citrate and cytokinin were procured from the agricultural commercial market.

### 3. Experimental setup and cultivation.

This experiment was carried out in a split-plot design with three replicates to assess the effects of above aforementioned stimulants at rate of 5 mg L<sup>-1</sup> for each one with volume of 900 L ha<sup>-1</sup> for each one, in addition to a control group that did not receive any spray on the studied pea cultivars (A, B and C) which were assigned to the main plots. The stimulants were arranged in the sub-main plots. This experimental setup allowed for evaluating the responses of different pea cultivars to the various stimulants in high-temperature conditions (in the last of August). Pea seeds were planted during the last week of August in both the 2020 and 2021 seasons. The sowing took place on two sides of the ridge in hilly areas with moderately moist soil, with an initial planting density of 3-4 seeds per hill. Thinning was carried out after germination and before the first irrigation, reducing the number of plants to two per hill. All agricultural practices for commercial pea production, including mineral and organic fertilization, were performed in accordance with the recommendations provided by the Egyptian Ministry of Agriculture. The cultivation followed a flood irrigation system. As for the studied stimulants (Vitamin C, melatonin, potassium citrate, and cytokinin), they were applied as foliar treatments twice during the growth period, specifically at 35 and 45 days after sowing.

### 4. Harvest Process.

The green pods were harvested at the appropriate stage of maturity for each of the different cultivars under study. The harvesting process took place at different time intervals, specifically after 80, 81, and 90 days from the date of sowing for the master b, sweet 1, and sweet 2 cultivars, respectively, during both seasons of investigation.

### 5. Measurement traits and statistical analysis

- At a period of 55 days after pea sowing some growth criteria, including plant height (cm), leaf area (cm<sup>2</sup> plant<sup>-1</sup>) and fresh and dry weights (g plant<sup>-1</sup>) as well as photosynthetic pigments *i.e.*, chlorophyll (SPAD reading value) and carotene (mg g<sup>-1</sup>, Kitada *et al.*, 1989) were determined. Also, days for fruit setting was calculated for the three cultivars.
- At harvest stage, yield and its components, including No. of pods, pod length (cm), weight of pods, weight of 100 seed (g), pods yield (ton ha<sup>-1</sup>) were determined as well as pods

quality characteristics including protein, carbohydrates, total sugars, total dissolved solids (TDS, %) and vitamin C mg 100 g<sup>-1</sup>(VC) were determined according to AOAC (2000).

- Statistical analysis was conducted according to Gomez and Gomez (1984), using CoStat (Version 6.303, CoHort, USA, 1998–2004)].

## RESULTS AND DISCUSSION

The results obtained, presented in the subsequent tables, demonstrate that the examined varieties (A, B, and C) and substances such as vitamin C, melatonin, potassium citrate, and cytokinin had a significant impact on the growth of peas. This impact was reflected in various aspects, including plant height (cm), leaf area (cm<sup>2</sup> plant<sup>-1</sup>), fresh and dry weights (g plant<sup>-1</sup>) (Table 1), chlorophyll reading (SPAD, value), carotene content (mg g<sup>-1</sup>), days for fruit setting (Table 2), No. of pods plant<sup>-1</sup>, pod length (cm), weight of pods (g) plant<sup>-1</sup>, weight of 100 seed (g), pods yield (metric ton ha<sup>-1</sup>) (Table 3), total protein, total carbohydrates, total sugars, TDS (%) and VC (mg 100g<sup>-1</sup>) (Table 4). These effects were observed during the seasons of 2020 and 2021.

The results showed that the cultivar "C" performed the best across all studied treatments, except for days required for fruit setting. Following "C" cultivar, the performance of cultivar "B" was observed to be superior, while cultivar "A" ranked third in terms of growth and yield characteristics. In terms of fruit setting, cultivars "A" and "B" exhibited early fruit setting, whereas cultivar "C" experienced a delay in fruit set. Regarding the foliar application of stimulants, cytokinin treatment yielded the highest values for all the studied growth and yield characteristics. Potassium citrate treatment ranked second in terms of performance, followed by melatonin and vitamin C treatments. The control group showed the lowest values for the measured parameters. Overall, the findings suggest that the application of cytokinin as a foliar treatment had the most positive impact on the growth and yield of pea plants under high-temperature conditions. Potassium citrate, melatonin, and vitamin C treatments also had positive effects, although to a lesser extent. The superiority of cultivar C (sweet 2), over other varieties (master b and sweet 1) can be attributed to that cultivar C (sweet 2) may possess genetic characteristics that make it more resilient and adapted to high-temperature circumstances. These traits could include heat tolerance, better water use efficiency, improved photosynthetic efficiency or enhanced stress response mechanisms. Cultivar C's delayed fruit setting may actually be advantageous under high-temperature circumstances. Late fruit set allows the pea plants to avoid extreme heat stress during the critical reproductive stage, ensuring better fruit development and yield. Cultivar C (sweet 2) might have a higher inherent yield potential compared to the other varieties (master b and sweet 1). It could produce more pods plant<sup>-1</sup>, larger pods, or a higher No. of seeds pod<sup>-1</sup>, resulting in increased overall yield. Cultivar C (sweet 2) could have a superior nutritional composition, with higher levels of important compounds such as proteins, carbohydrates, vitamins and total sugars. This could contribute to improved plant growth and productivity. Cultivar C (sweet 2) may exhibit better resistance to common pests and diseases prevalent in high-temperature circumstances. This resistance helped in protecting the pea plants from damage, reducing yield losses and the need for excessive pesticide use. Cultivar C (sweet 2) may possess desirable agronomic characteristics including better branching, improved root system, higher leaf area, or

efficient nutrient uptake. These traits contribute to overall plant vigor and productivity. It is possible that cultivar C (sweet 2) responded more favorably to specific management practices like the application of the studied stimulants or optimized irrigation and fertilization strategies. These practices could enhance its growth and yield potential. The obtained results are in harmony with those of (Ghazi and Ahmed, 2022).

The control treatment, without any stimulant application, serves as a baseline reference. It lacks the additional benefits provided by the studied stimulants, resulting in lower growth performance and yield characteristics compared to the treated groups. The ranking of the treatments in the following order: Cytokinin, potassium citrate, melatonin, vitamin C, and control, could be attributed to the specific effects and mechanisms of action of each treatment. Cytokinin came in the first order and this may be attributed to its vital role in promoting cell division and expansion. Also, it can enhance shoot development, increase the number and size of pods, and stimulate overall biomass production. on the other hand, it might influence various hormonal pathways in the studied cultivars of the pea plants, including auxin and gibberellin, which are involved in regulating pea plants' growth and development. This hormonal regulation may contribute to the observed superior growth performance and yield characteristics. Also, in this respect, cytokinin can have positive impacts on flowering and fruit sets, leading to improved yield. It may stimulate flower initiation and prolong the flowering period as well as enhance fruit development and retention. The findings obtained are consistent with those of Mok (2019).

Potassium citrate came in the second order for enhancing the growth performance and yield, as it outperformed the other studied stimulants, except cytokinin, due to potassium (K) being an essential macronutrient for pea plants growth and

development, where potassium citrate provides a readily available form of potassium for pea plants, promoting healthy pea plant growth performance and improving various physiological processes. Also, K plays a crucial role in regulating osmotic potential in pea plant cells, maintaining turgor pressure, and facilitating water movement within the plant. This can help plants cope with high-temperature stress and optimize their physiological functions (El-Sherpiny *et al.*, 2022). On the other hand, it is involved in the activation of numerous enzymes, which are essential for metabolic processes. Finally, this can affect various biochemical reactions related to growth performances, thus yield, and nutrient uptake. The obtained results are in agreement with the findings reported by previous studies conducted by Gebaly *et al.*, (2013); Soliman *et al.*, (2022).

Melatonin is arranged in the third order due to it acts as a powerful antioxidant in pea plants, helping to scavenge ROS and reduce oxidative damage caused by high-temperature stress, thus protecting plant cells and improving overall growth performance, yield and its components. Moreover, it can modulate stress-responsive proteins as well as regulate gene expression and thus improving pea plants' tolerance to heat stress. The obtained results align with those of Yusuf *et al.* (2020).

Vitamin C came in penultimate order because it functions as a widely recognized antioxidant that counteracts ROS and safeguards plant cells against oxidative harm induced by heat stress. It plays a crucial role in numerous biochemical mechanisms, including photosynthesis. By enhancing the performance of the photosynthetic system, it has the capacity to improve carbon assimilation, enhance biomass generation, and ultimately increase crop yield. The obtained results are in harmony with those of Noufal (2018). The same trend was found for both studied seasons.

**Table 1. Comparison of growth performance of three pea cultivars with different stimulants over a 55-day period from sowing in the seasons of 2020 and 2021**

**CONCLUSION**

According to the obtained results, cultivar C (sweet 2) consistently outperformed the other cultivars across all studied treatments, except for days required for fruit setting. Cultivar B (sweet 1) demonstrated superior performance compared to cultivar A (master b). In terms of fruit setting, cultivars A (master b) and B (sweet 1) exhibited early fruit setting, while cultivar C (sweet 2) experienced a delay in fruit set. Cytokinin resulted in the highest values for all measured growth and yield parameters. Potassium citrate ranked second, followed by melatonin and vitamin C. Based on these findings, it can be concluded that cytokinin application as a foliar treatment had the most significant positive impact on the growth and yield of pea plants under high-temperature conditions. Potassium citrate, melatonin, and vitamin C treatments also had beneficial effects, albeit to a lesser extent. Despite the fact that Master B and Sweet 1 cultivars exhibit lower vegetative growth and productivity compared to the Sweet 2 cultivar, they have the advantage of early maturation. As a result, these cultivars can potentially generate higher economic profits than the Sweet A variety, which ripens later.

**RECOMMENDATIONS**

1. Farmers and growers cultivating pea plants in high-temperature conditions should consider using cultivar C (sweet 2), as it demonstrated superior performance in terms of growth and yield compared to cultivars A (master b) and B (sweet 1).
2. Cytokinin can be recommended as an effective stimulant for foliar application to enhance the growth and yield of pea plants under high-temperature conditions. Its application should be considered during critical growth stages.
3. Potassium citrate, melatonin, and vitamin C can also be utilized as stimulants, although their effects were not as pronounced as

cytokinin. Farmers may consider using these stimulants as supplementary treatments to improve growth and yield.

4. Further research is warranted to investigate the optimal application rates and timings of the stimulants under varying high-temperature conditions. Additionally, exploring the synergistic effects of combining multiple stimulants could be beneficial.
5. It is advisable to conduct similar experiments in different locations and seasons to validate the findings and assess the consistency of the stimulant effects on different pea cultivars.

## تأثير بعض المعاملات المحفزة للنمو والمحصول على نباتات البسلة المنزرعة تحت ظروف الحرارة المرتفعة

هدى إبراهيم احمد إبراهيم والسيد البدوي إبراهيم طه

معهد بحوث البساتين – مركز البحوث الزراعية – مصر

### المخلص

لدراسة تأثير بعض المعاملات المحفزة على نباتات البسلة النامية تحت ظروف درجات الحرارة العالية، تم إجراء تجربة حقلية لتقييم تأثير حمض الأسكوربيك والميلاتونين وسترات البوتاسيوم والسايكوكينين، بالإضافة إلى معاملة الكنترول التي لم تتلقى أي رش، على الأصناف A (الماستر بي) و B (السويت 1) و C (السويت 2) من البازلاء، والتي تم توزيعها في القطع الرئيسية. بينما تم ترتيب المعاملات في القطع الفرعية المنشقة. تم قياس مختلف معايير النمو والإنتاجية، مثل ارتفاع النبات، والمساحة الورقية، والأوزان الطازجة والجافة، ومحتوى الكلوروفيل، ومحتوى الكاروتين، والفترة الواجبة للعد، وعدد القرون، وطول القرون، ومحصول القرون ومحتوى البروتين. أظهرت النتائج أن الصنف "C" كان الأفضل في جميع المعاملات المدروسة، باستثناء الفترة الواجبة للعد. بعد الصنف "C"، لوحظ أن أداء الصنف "B" كان أفضل، في حين احتل الصنف "A" المركز الثالث من حيث خصائص النمو والإنتاجية. من حيث الفترة الواجبة للعد، أظهر الصنفان "A" و "B" عتدا مبكراً للثمار، بينما تأخر العتد مع الصنف "C". بالنسبة للمحفات، أعطى الرش بالسايكوكينين أعلى قيم لجميع الخصائص المدروسة. بينما جالت معاملة سترات البوتاسيوم في المرتبة الثانية من حيث الأداء، تليها معاملة الميلاتونين وفيتامين سي على الترتيب. بينما أعطت معاملة الكنترول أقل القيم. بشكل عام، كان لتطبيق السايكوكينين التأثير الأكثر إيجابية على نمو وإنتاج نباتات البسلة تحت ظروف درجات الحرارة العالية. كان للمنشطات المدروسة الأخرى أيضاً تأثيرات إيجابية، وإن كانت بدرجة أقل.
